Drought – Increased demand on the clean water supply

ARE WE DOING RIGHT BY DOMESTIC WATER?

We depend on water for our very existence. It is time to re-evaluate how we waste power and resources, namely pumping and treating water before and after we use it, and yes the infrastructure that supports it all is no small matter.

Ib V. Andersen, inventor of ENVIROSINK® believes the reuse of gray water is a cost effective alternative to dumping clean water down the drain only to have it treated as sewage. Reuse of gray water benefits all of the environment, and us.

ENVIROSINK is the only system that allows some catchment of water from the kitchen sink. A family of three can save an average of 18 gallons of perfectly useable water per day – or 3.3% of all water used in the home! Waiting for hot or cold water, washing and rinsing fruits and vegetables – just about everything you do at the kitchen sink, clean wastewater can be saved.

**If indeed every drop counts,
And we believe that it does,
Then maybe it's time we use all the tools AVAILABLE.**

ENVIROSINK should be included in all-new homes and renovation plans. All types of home construction should have **gray water recycling systems**.
